薄膜的等倾干涉

薄膜等厚干涉

劈尖干涉 牛顿环

3.3.1 等倾干涉

点光源照明时的干涉条纹分析

光束 1、2 的光程差：

$$\delta = n(\overline{AB} + \overline{BC}) - n' \overline{AD} + \frac{\lambda}{2}$$

$$\overline{AB} = \overline{BC} = \frac{e}{\cos r}$$

$$\overline{AD} = \overline{AC} \sin i$$

$$= 2e \operatorname{tg} r \sin i$$

$$\delta = n(\overline{AB} + \overline{BC}) - n' \overline{AD} + \frac{\lambda}{2}$$

$$\overline{AB} = \overline{BC} = \frac{e}{\cos r}$$

$$\begin{aligned} \overline{AD} &= \overline{AC} \sin i \\ &= 2e \operatorname{tg} r \sin i \end{aligned}$$

$$\therefore \delta = \frac{2ne}{\cos r} - \frac{2n'e \cdot \sin r \cdot \sin i}{\cos r} + \frac{\lambda}{2}$$

$$n' \sin i = n \sin r \quad \therefore \delta = \frac{2ne}{\cos r} - \frac{2ne \cdot \sin^2 r}{\cos r} + \frac{\lambda}{2}$$

$$\delta = 2ne \cos r + \frac{\lambda}{2} \qquad \delta = \frac{2ne}{\cos r} - \frac{2ne \cdot \sin^2 r}{\cos r} + \frac{\lambda}{2}$$

用入射角表示

$$\delta = 2ne \sqrt{1 - \sin^2 r} + \frac{\lambda}{2} \qquad n' \sin i = n \sin r$$

$$\delta = 2e \sqrt{n^2 - n'^2 \sin^2 i} + \frac{\lambda}{2}$$

$$\delta = 2e\sqrt{n^2 - n'^2 \sin^2 i} + \frac{\lambda}{2}$$

空气中

$$\delta = 2e\sqrt{n^2 - \sin^2 i} + \frac{\lambda}{2} \quad \lambda、n \text{ 一定, } \delta = \delta(i)$$

$$\delta(i) = k\lambda, \quad k = 1, 2, 3, \dots \quad \text{明纹}$$

$$\delta(i) = (2k' + 1)\frac{\lambda}{2}, \quad k' = 0, 1, 2, \dots \quad \text{暗纹}$$

倾角 i 相同的光线对应同一条干涉条纹
——等倾条纹

注意：

1 忽略三、五、…次反射，因其强度较第一次反射弱得多

2 透射光也有干涉现象

$$\text{无附加光程差 } \delta = 2e \sqrt{n^2 - \sin^2 i}$$

花纹亮暗与在反射光中观察到的相反

面光源照明时，干涉条纹的分析

$$\delta = 2e\sqrt{n^2 - \sin^2 i} + \frac{\lambda}{2}$$

只要入射角 i 相同，
都将汇聚在同一个
干涉环上（**非相干
叠加**）

$$\delta(i) = k\lambda, \quad k = 1, 2, 3, \dots \quad \text{明纹}$$

$$\delta(i) = (2k + 1)\frac{\lambda}{2}, \quad k = 0, 1, 2, \dots \quad \text{暗纹}$$

明暗相间的圆形花纹

讨论:

$$\delta = 2ne \cos r + \frac{\lambda}{2}$$

1) 当 e 一定时, $\delta(r)$

$i(r) \downarrow$, $\cos r \uparrow$, $\delta \uparrow$, $k \uparrow$

越靠近中心, 环的干涉级次越高

中心处: $r = 0$

$$\delta = 2ne + \frac{\lambda}{2}$$

$\left\{ \begin{array}{l} = k\lambda, \quad k = 1, 2, 3, \dots \quad \text{明纹} \end{array} \right.$

$\left\{ \begin{array}{l} = (2k' + 1)\frac{\lambda}{2}, \quad k' = 0, 1, 2, \dots \quad \text{暗纹} \end{array} \right.$

2) $e \uparrow, k \uparrow$

中心不断**冒**出花纹，原亮纹不断向外扩大

$$\delta = 2ne \cos r + \frac{\lambda}{2}$$

设某时刻中心 k_c 级亮斑

$$\delta = 2ne + \frac{\lambda}{2} = k_c \lambda$$

$e \uparrow \rightarrow$ 中心变**暗** $\rightarrow$ 变**亮**

$$\delta = 2ne' + \frac{\lambda}{2} = (k_c + 1)\lambda$$

$$\Delta e = e' - e = \frac{\lambda}{2n}$$

中心每**冒**出一个亮斑，厚

$$\text{度增加} = \frac{\lambda}{2n}$$

$e \downarrow$ 亮环一个个地向中心**缩**进，中心亮斑一个个地消失， e 每减少 $\lambda / 2n$ ，中心就有一个亮斑消失。

3) 相邻亮斑角间距

$$2ne \cos r + \frac{\lambda}{2} = k\lambda$$

$$- 2ne \sin r \Delta r = \Delta k \lambda$$

$$\Delta k = 1$$

$$- \Delta r = \frac{\lambda}{2ne \sin r}$$

e 越大, Δr 越小, 相邻亮纹间的距离越小, 条纹越密, 越不容易辨认。 r 越大, 越靠外, Δr 越小, 条纹越密, 花样内疏外密。

应用：增透（反）膜

在光学仪器上镀膜, 使某种波长的反射光或透射光因干涉而减少或加强, 以提高仪器反射率或透射率

增透膜($n_1 < n < n_2$) : 当单色光垂直入射薄膜表面时, 在上下表面反射形成相干光2、3, 都有半波损失, 其光程差为

$$\delta = 2ne = (2k + 1)\lambda / 2 \quad k = 0, 1, 2, 3 \dots$$

两束光相干减弱, 因2、3光强有差别, 故不会完全相消, 使反射光减弱, 由能量守恒, 透射光必定增强。

**镜片左边涂有抗反射涂层
右边则没有抗反射涂层**

[例]:透镜($n_3=1.5$)表面涂有**增透膜**($\text{MgF}_2:n_2=1.38$)

为了让人眼最敏感的黄绿光 $\lambda=550\text{nm}$ 尽可能透过, 镀的膜厚度为多少?

解法一: 反射光相消

$$\delta = 2en_2 = (2k + 1)\frac{\lambda}{2}$$

(有二次半波损失)

$$\delta = 2en_2 = (2k + 1)\frac{\lambda}{2}$$

$$k=0,1,2,\dots\text{暗}$$

$$e = \frac{(2k + 1)\lambda}{4n_2} = (2k + 1) \times 9.96 \times 10^{-8} [\text{m}]$$

$$k=0,1,2,\dots$$

上面的计算只考虑了反射光的相差对干涉的影响。
实际上能否完全相消，还要看两反射光的振幅。

解法二：透射光加强

$$\delta = 2n_2e + \frac{\lambda}{2} = k\lambda$$

$$k=1,2,\dots$$

(有一次半波损失)

$$e = \frac{(2k-1)\lambda}{4n_2} = (2k-1) \times 9.96 \times 10^{-8} [\text{m}]$$

$$k=1,2,\dots$$

增反膜：也可以利用适当厚度的介质膜来加强反射光，由于反射光一般较弱，实际上利用多层介质膜来制成高反射膜。

应用：蝴蝶翅膀上的虹彩

(a)在电子显微镜下观察闪蝶翅膀

(b)光线从两个阶梯状阻挡处反射，相长干涉产生了翅膀上的蓝色

(c)发生干涉的另外两对光线
